# C++11, 14, 17

- Most of what we have taught you in this class are language features that were part of C++ since the C++98 standard
- New, helpful features have been added in C++11, 14, and now 17 standards
  - Beware: compilers are often a bit slow to implement the standards so check the documentation and compiler version
  - You often must turn on special compile flags to tell the compiler to look for C++11 features, etc.
    - For g++ you would need to add: `-std=c++11` or `-std=c++0x`
- Many of the features in the next C++11 are part of a 3<sup>rd</sup> party library called Boost

Plugging the leaks

# **SMART POINTERS**

# Pointers or Objects? Both!

- In C++, the dereference operator (\*) should appear before...
  - A pointer to an object
  - An actual object
- "Good" answer is
  - A Pointer to an object
- "Technically correct" answer...
  - EITHER!!!!
- Due to operator overloading we can make an object behave as a pointer
  - Overload operator \*, &, ->, ++, etc.

```
class Thing
{
};

int main()
{
    Thing t1;
    Thing *ptr = &t1

    // Which is legal?
    *t1;
    *ptr;
}
```

# A "Dumb" Pointer Class

- We can make a class operate like a pointer
- Use template parameter as the type of data the pointer will point to
- Keep an actual pointer as private data
- Overload operators
- This particular class doesn't really do anything useful
  - It just does what a normal pointer would do

```
template <typename T>
class dumb_ptr
{ private:
    T* p_;
public:
    dumb_ptr(T* p) : p_(p) { }
    T& operator*() { return *p_; }
    T* operator->() { return p_; }
    dumb_ptr& operator++() // pre-increment
    { ++p_; return *this; }
};

int main()
{
    int data[10];
    dumb_ptr<int> ptr(data);

    for(int i=0; i < 10; i++) {
        cout << *ptr;  ++ptr;
    }
}
```

# A "Useful" Pointer Class

- I can add automatic memory deallocation so that when my local "unique\_ptr" goes out of scope, it will automatically delete what it is pointing at

```
template <typename T>
class unique_ptr
{ private:
    T* p_;
public:
    unique_ptr(T* p) : p_(p) { }
    ~unique_ptr() { delete p_; }
    T& operator*() { return *p_; }
    T* operator->() { return p_; }
    unique_ptr& operator++() // pre-increment
        { ++p_; return *this; }
};

int main()
{
    unique_ptr<Obj> ptr(new Obj);
    // ...
    ptr->all_words()
    // Do I need to delete Obj?
}
```

# A "Useful" Pointer Class

- What happens when I make a copy?
- Can we make it impossible for anyone to make a copy of an object?
  - Remember C++ provides a default "shallow" copy constructor and assignment operator

```
template <typename T>
class unique_ptr
{ private:
    T* p_;
public:
    unique_ptr(T* p) : p_(p) { }
    ~unique_ptr() { delete p_; }
    T& operator*() { return *p_; }
    T* operator->() { return p_; }
    unique_ptr& operator++() // pre-incre
    { ++p_; return *this; }
};

int main()
{
    unique_ptr<Obj> ptr(new Obj);
    unique_ptr<Obj> ptr2 = ptr;
    // ...
    ptr2->all_words();
    // Does anything bad happen here?
}
```

# Hiding Functions

- Can we make it impossible for anyone to make a copy of an object?
  - Remember C++ provides a default "shallow" copy constructor and assignment operator
- Yes!!
  - Put the copy constructor and operator= declaration in the private section...now the implementations that the compiler provides will be private (not accessible)
- You can use this technique to hide "default constructors" or other functions

```
template <typename T>
class unique_ptr
{ private:
    T* p_;
public:
    unique_ptr(T* p) : p_(p) { }
    ~unique_ptr() { delete p_; }
    T& operator*() { return *p_; }
    T* operator->() { return p_; }
    unique_ptr& operator++() // pre-incre
        { ++p_; return *this; }
private:
    unique_ptr(const UsefullPtr& n);
    unique_ptr& operator=(const
                           UsefullPtr& n);
};

int main()
{
    unique_ptr<Obj> ptr(new Obj);
    unique_ptr<Obj> ptr2 = ptr;
    // Try to compile this?
}
```

# A "shared" Pointer Class

- Could we write a pointer class where we can make copies that somehow "know" to only delete the underlying object when the last copy of the smart pointer dies?
- Basic idea
  - shared\_ptr class will keep a count of how many copies are alive
  - shared\_ptr destructor simply decrements this count
    - If count is 0, delete the object

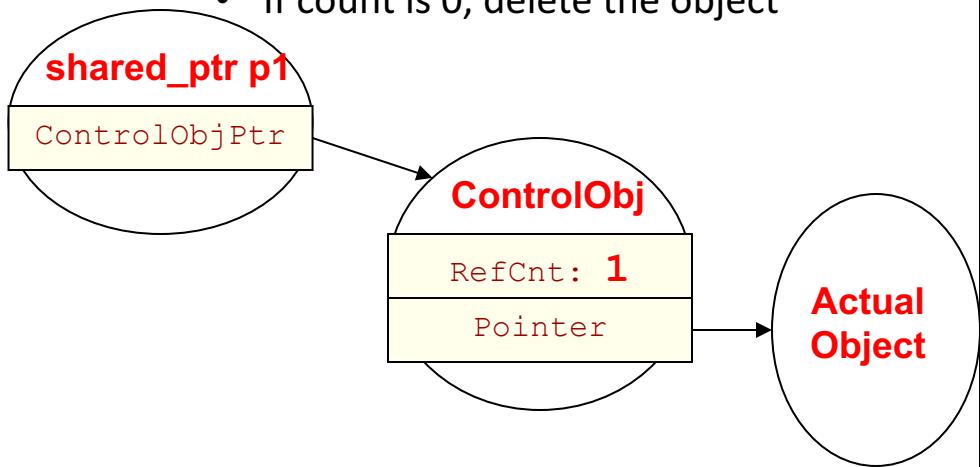

```
template <typename T>
class shared_ptr
{ public:
    shared_ptr(T* p);
    ~shared_ptr();
    T& operator*();
    shared_ptr& operator++();
}

shared_ptr<Obj> f1()
{
    shared_ptr<Obj> ptr(new Obj);
    cout << "In F1\n" << *ptr << endl;
    return ptr;
}

int main()
{
    shared_ptr<Obj> p2 = f1();
    cout << "Back in main\n" << *p2;
    cout << endl;
    return 0;
}
```

# A "shared" Pointer Class

- Basic idea
  - `shared_ptr` class will keep a count of how many copies are alive
  - Constructors/copies increment this count
  - `shared_ptr` destructor simply decrements this count
    - If count is 0, delete the object

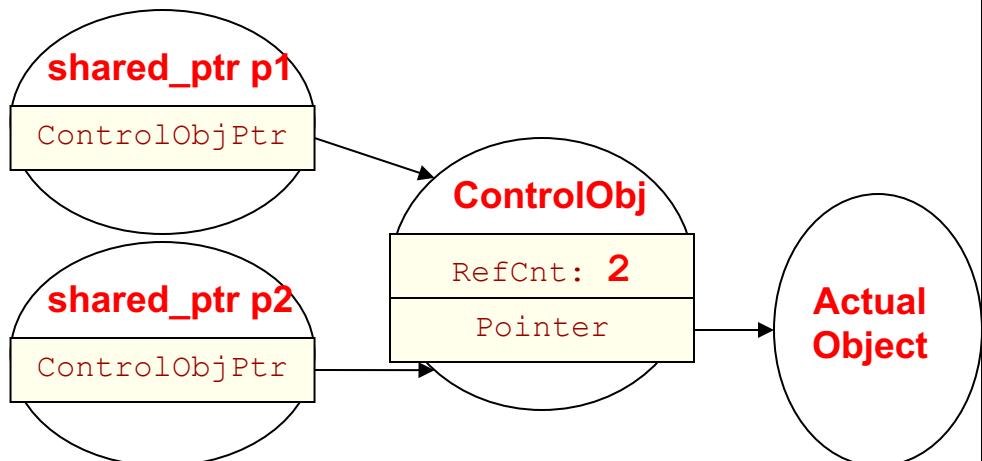

```
int main()
{
    shared_ptr<Obj> p1(new Obj);
    doit(p1);
    return 0;
}

void doit(shared_ptr<Obj> p2)
{
    if(...){
        shared_ptr<Obj> p3 = p2;
    }
}
```

# A "shared" Pointer Class

- Basic idea
  - `shared_ptr` class will keep a count of how many copies are alive
  - `shared_ptr` destructor simply decrements this count
    - If count is 0, delete the object

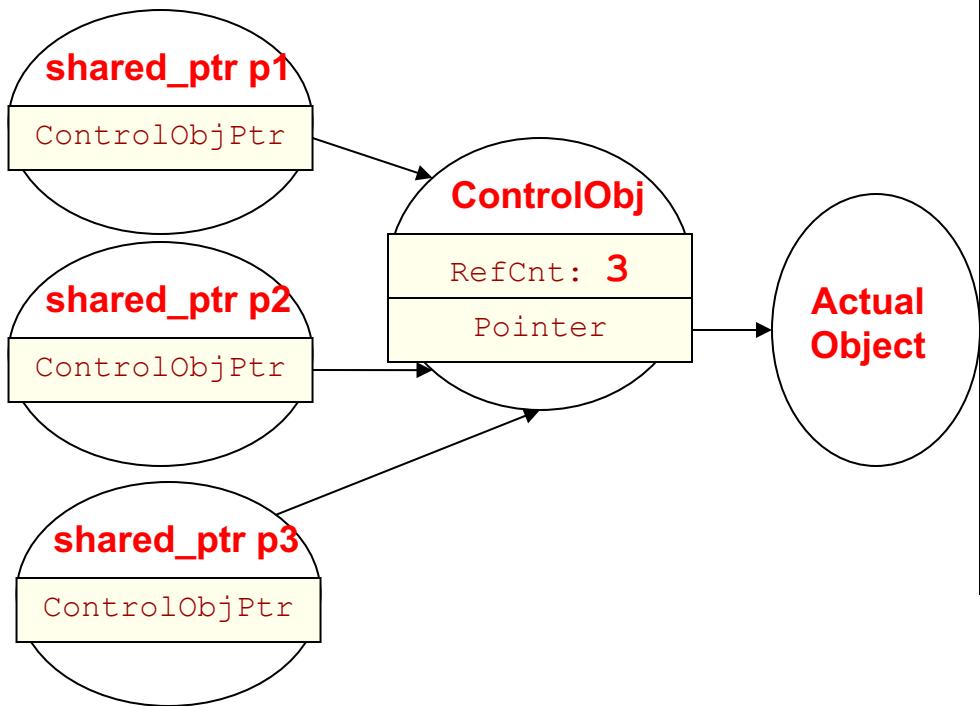

```
int main()
{
    shared_ptr<Obj> p1(new Obj);
    doit(p1);
    return 0;
}

void doit(shared_ptr<Obj> p2)
{
    if(...){
        shared_ptr<Obj> p3 = p2;
    }
}
```

# A "shared" Pointer Class

- Basic idea
  - `shared_ptr` class will keep a count of how many copies are alive
  - `shared_ptr` destructor simply decrements this count
    - If count is 0, delete the object

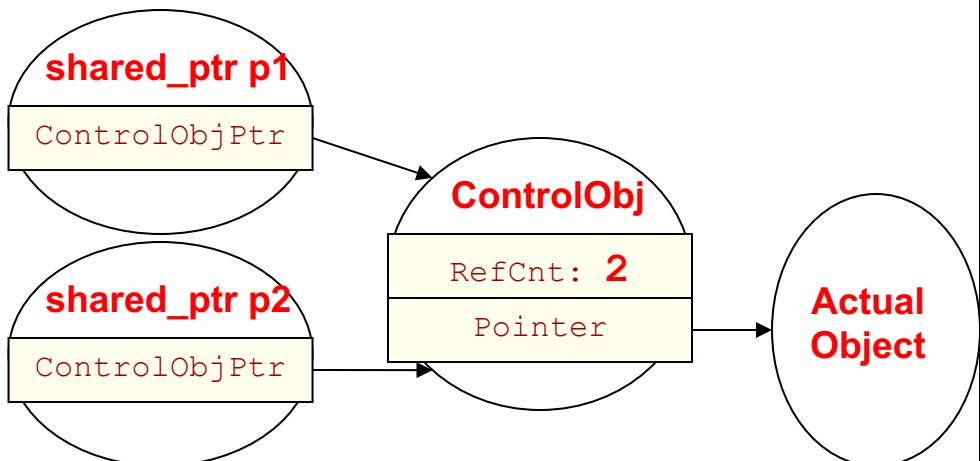

```
int main()
{
    shared_ptr<Obj> p1(new Obj);
    doit(p1);
    return 0;
}

void doit(shared_ptr<Obj> p2)
{
    if(...){
        shared_ptr<Obj> p3 = p2;
    }
}
```

# A "shared" Pointer Class

- Basic idea
  - `shared_ptr` class will keep a count of how many copies are alive
  - `shared_ptr` destructor simply decrements this count
    - If count is 0, delete the object

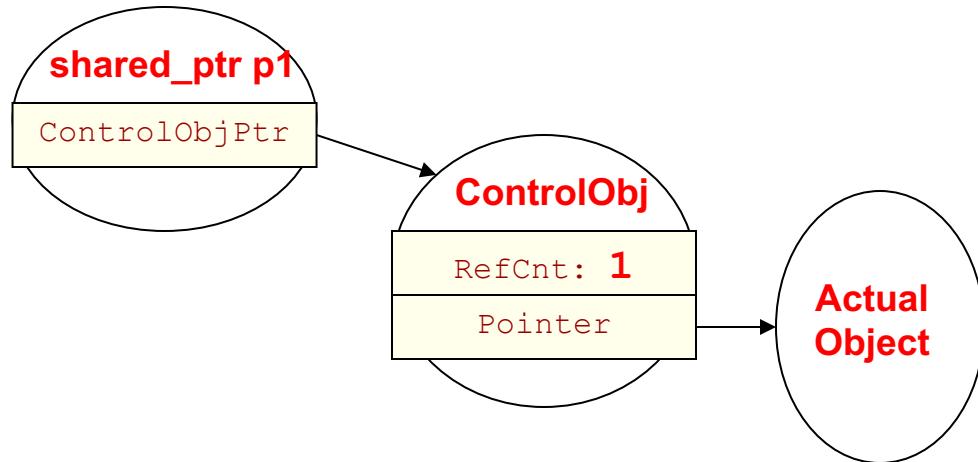

```
int main()
{
    shared_ptr<Obj> p1(new Obj);
    doit(p1);
    return 0;
}

void doit(shared_ptr<Obj> p2)
{
    if(...){
        shared_ptr<Obj> p3 = p2;

    } // p3 dies
}
```

# A "shared" Pointer Class

- Basic idea
  - shared\_ptr class will keep a count of how many copies are alive
  - shared\_ptr destructor simply decrements this count
    - If count is 0, delete the object

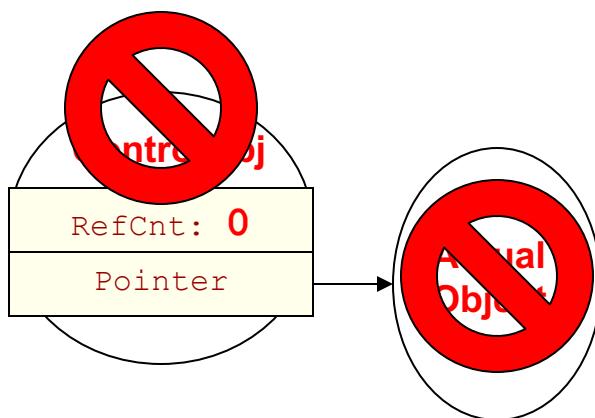

```
int main()
{
    shared_ptr<Obj> p1(new Obj);
    doit(p1);
    return 0;
}

void doit(shared_ptr<Obj> p2)
{
    if(...){
        shared_ptr<Obj> p3 = p2;

    } // p3 dies
} // p2 dies
```

# A "shared" Pointer Class

- Basic idea
  - shared\_ptr class will keep a count of how many copies are alive
  - shared\_ptr destructor simply decrements this count
    - If count is 0, delete the object

```
int main()
{
    shared_ptr<Obj> p1(new Obj);
    doit(p1);
    return 0;
} // p1 dies

void doit(shared_ptr<Obj> p2)
{
    if(...){
        shared_ptr<Obj> p3 = p2;

    } // p3 dies
} // p2 dies
```

# C++ shared\_ptr

- C++ std::shared\_ptr / boost::shared\_ptr
  - Boost is a best-in-class C++ library of code you can download and use with all kinds of useful classes
- Can only be used to point at dynamically allocated data (since it is going to call delete on the pointer when the reference count reaches 0)
- Compile in g++ using '-std=c++11' since this class is part of the new standard library version

```
#include <memory>
#include "obj.h"
using namespace std;

shared_ptr<Obj> f1()
{
    shared_ptr<Obj> ptr(new Obj);
    // ...
    cout << "In F1\n" << *ptr << endl;
    return ptr;
}

int main()
{
    shared_ptr<Obj> p2 = f1();
    cout << "Back in main\n" << *p2;
    cout << endl;
    return 0;
}
```

\$ g++ -std=c++11 shared\_ptr1.cpp obj.cpp

# C++ shared\_ptr

- Using shared\_ptr's you can put pointers into container objects (vectors, maps, etc) and not have to worry about iterating through and deleting them
- When myvec goes out of scope, it deallocates what it is storing (shared\_ptr's), but that causes the shared\_ptr destructor to automatically delete the Obj's
- Think about your project homeworks...this might be (have been) nice

```
#include <memory>
#include <vector>
#include "obj.h"
using namespace std;

int main()
{
    vector<shared_ptr<Obj> > myvec;

    shared_ptr<Obj> p1(new Obj);
    myvec.push_back( p1 );

    shared_ptr<Obj> p2(new Obj);
    myvec.push_back( p2 );

    return 0;
// myvec goes out of scope...
}
```

\$ g++ -std=c++11 shared\_ptr1.cpp obj.cpp

# shared\_ptr vs. unique\_ptr

- Both will perform automatic deallocation
- Unique\_ptr only allows one pointer to the object at a time
  - Copy constructor and assignment operator are hidden as private functions
  - Object is deleted when pointer goes out of scope
  - Does allow "move" operation
    - If interested read more about this on your own
    - C++11 defines "move" constructors (not just copy constructors) and "rvalue references" etc.
- Shared\_ptr allow any number of copies of the pointer
  - Object is deleted when last pointer copy goes out of scope
- Note: Many languages like python, Java, C#, etc. all use this idea of reference counting and automatic deallocation (aka garbage collection) to remove the burden of memory management from the programmer

# ITERATORS

# Iteration

- Consider how you iterate over all the elements in a list
  - Use a for loop and get() or operator[]
- For an array list this is fine since each call to get() is O(1)
- For a linked list, calling get(i) requires taking i steps through the linked list
  - 0<sup>th</sup> call = 0 steps
  - 1<sup>st</sup> call = 1 step
  - 2<sup>nd</sup> call = 2 steps
  - $0+1+2+\dots+n-2+n-1 = O(n^2)$
- You are repeating the work of walking the list...

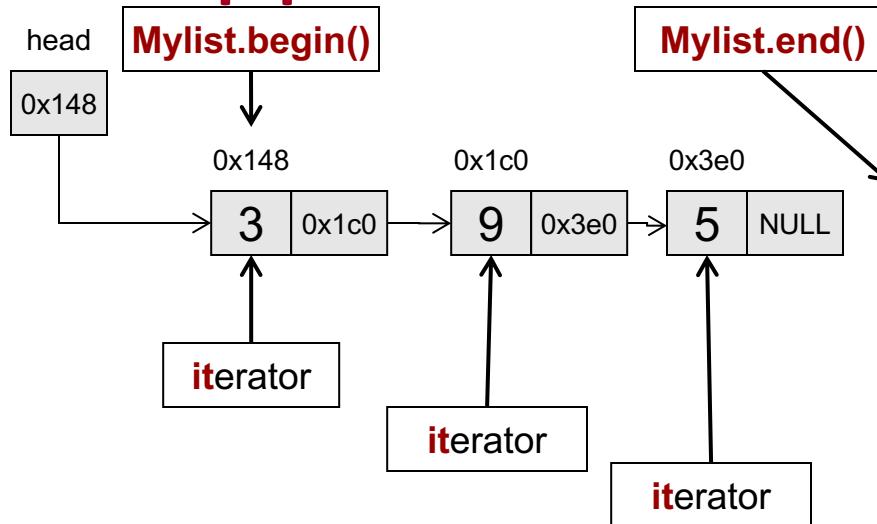

```
ArrayList<int> mylist;
...
for(int i=0; i < mylist.size(); ++i)
{
    cout << mylist.get(i) << endl;
}
```

```
LinkedList<int> mylist;
...
for(int i=0; i < mylist.size(); ++i)
{
    cout << mylist.get(i) << endl;
}
```

# Iteration: A Better Approach

- Solution: Don't use get(i)
- Use an **iterator**
  - Stores internal state variable (i.e. another pointer) that remembers where you are and allows taking steps efficiently
- Iterator tracks the internal location of each successive item
- Iterators provide the semantics of a pointer (they look, smell, and act like a pointer to the values in the list)
- Assume
  - Mylist.begin() returns an "iterator" to the beginning item
  - Mylist.end() returns an iterator "one-beyond" the last item
  - ++it (prefered) or it++ moves iterator on to the next value

```
LinkedList<int> mylist;
...
iterator it = mylist.begin();
for(it = mylist.begin();
    it != mylist.end();
    ++it)
{
    cout << *it << endl;
}
```

# Why Iterators

- Can be more efficient
  - Keep internal state variable for where you are in your iteration process so you do NOT have to traverse (re-walk) the whole list every time you want the next value
- Hides the underlying implementation details from the user
  - User doesn't have to know whether its an array or linked list behind the scene to know how to move to the next value
    - To take a step with a pointer in array: `++ptr`
    - To take a step with a pointer in a linked list: `ptr = ptr->next`
  - For some of the data structures like a BST the underlying structure is more complex and to go to the next node in a BST is not a trivial task

More operator overloading...

# DEFINING ITERATORS

# A "Dumb" Pointer Class

- Operator\*
  - Should return reference ( $T\&$ ) to item pointed at
- Operator->
  - Should return a pointer ( $T^*$ ) to item be referenced
- Operator++()
  - Preincrement
  - Should return reference to itself iterator& (i.e. return  $*this$ )
- Operator++(int)
  - Postincrement
  - Should return another iterator pointing to current item will updating itself to point at the next
- Operator== & !=

```
template <typename T>
class DumbPtr
{ private:
    T* p_;
public:
    DumbPtr(T* p) : p_(p) { }
    T& operator*() { return *p_; }
    T* operator->() { return p_; }
    DumbPtr& operator++() // pre-inc
    { ++p_; return *this; }
    DumbPtr operator++(int) // post-inc
    { DumbPtr x; x.p_ = p_; ++p_; return x; }
    bool operator==(const DumbPtr& rhs);
    { return p_ == rhs.p_; }
    bool operator!=(const DumbPtr& rhs);
    { return p_ != rhs.p_; }
};

int main()
{
    int data[10];
    DumbPtr<int> ptr(data);

    for(int i=0; i < 10; i++){
        cout << *ptr;  ++ptr;
    }
}
```

# Pre- vs. Post-Increment

- Recall what makes a function signature unique is combination of name AND number/type of parameters
  - int f1() and void f1() are the same
  - int f1(int) and void f1() are unique
- When you write: obj++ or ++obj the name of the function will be the same: operator++
- To differentiate the designers of C++ arbitrarily said, we'll pass a dummy int to the operator++() for POST-increment
- So the prototypes look like this...
  - Preincrement: iterator& operator++();
  - Postincrement: iterator operator++(int);
    - Prototype the 'int' argument, but ignore it...never use it...
    - It's just to differentiate pre- from post-increment

# Pre- vs. Post-Increment

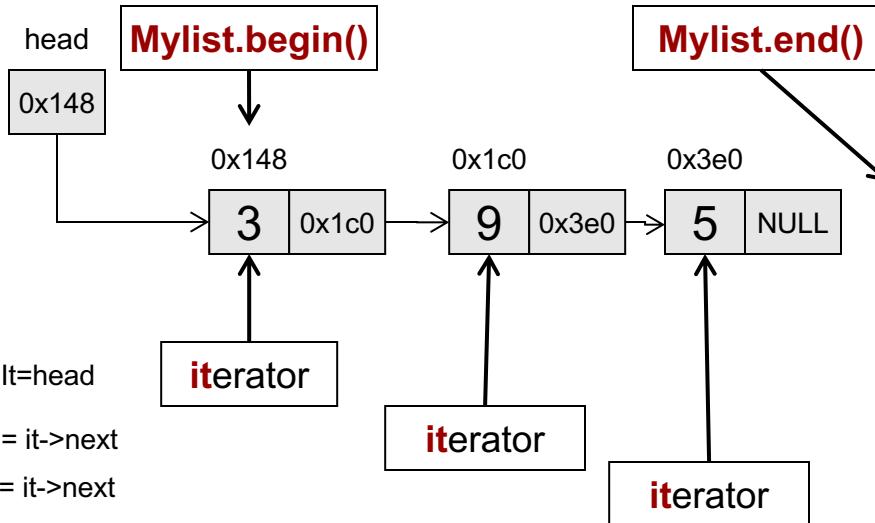

- Consider an expression like the following ( $a=1$ ,  $b=5$ ):
  - $(a++ * b) + (a * ++b)$
  - $1*5 + 2*6$
  - Operator++ has higher precedence than multiply (\*), so we do it first but the post increment means it should appear as if the old value of a is used
  - To achieve this, we could have the following kind of code:
    - $a++ \Rightarrow \{ \text{int } x = a; a = a+1; \text{return } x; \}$ 
      - Make a copy of a (which we will use to evaluate the current expr.)
      - Increment a so its ready to be used the next time
      - Return the copy of a that we made
    - Preincrement is much easier because we can update the value and then just use it
    - $++b \Rightarrow \{ b = b+1; \text{return } b; \}$
  - Takeaway: Post-increment is "less efficient" because it causes a copy to be made

# Exercise

- Add an iterator to the supplied linked list class
  - \$ mkdir iter\_ex
  - \$ cd iter\_ex
  - \$ wget <http://ee.usc.edu/~redekopp/cs104/iter.tar>
  - \$ tar xvf iter.tar

# Building Our First Iterator

- Let's add an iterator to our Linked List class
  - Will be an object/class that holds some data that allows us to get an item in our list and move to the next item
  - How do you iterate over a linked list normally:
    - Item<T>\* temp = head;**
    - While(temp) temp = temp->next;**
  - So my iterator object really just needs to model (contain) that 'temp' pointer
- Iterator needs following operators:
  - \*
  - >
  - ++
  - == / !=
  - < ??

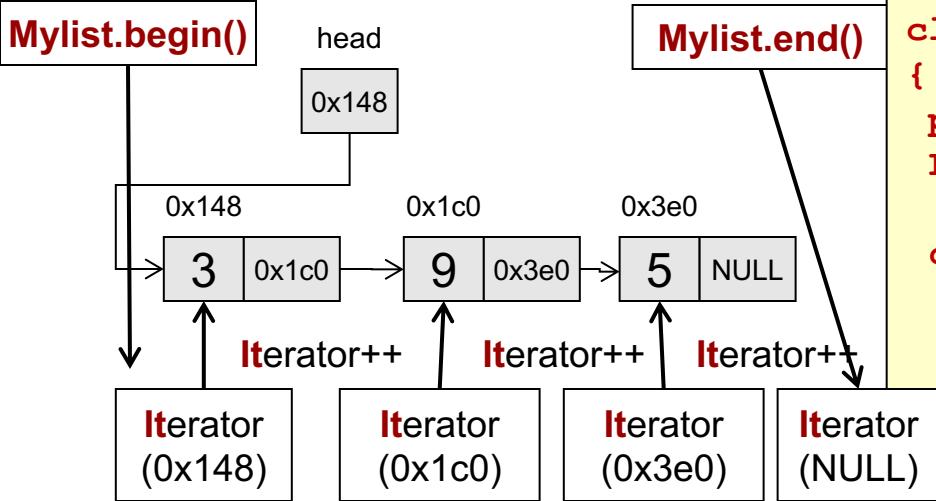

```
template <typename T>
struct Item {
    T val;
    Item<T>* next;
};

template <typename T>
class LList {
public:
    LList(); // Constructor
    ~LList(); // Destructor

private:
    Item<T>* head_;
};
```

# Implementing Our First Iterator

- We store the Item<T> pointer to our current item/node during iteration
- We return the value in the Item when we dereference the iterator
- We update the pointer when we increment the iterator

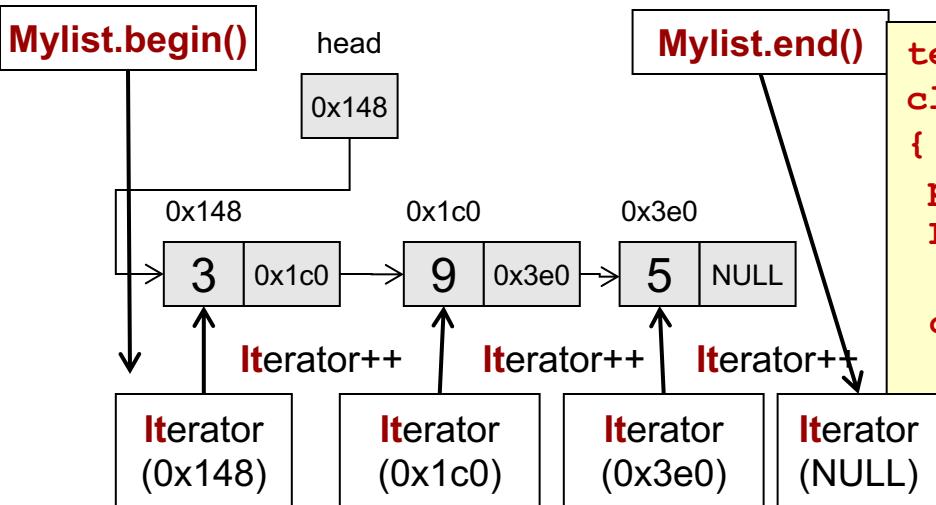

```
template<typename T>
class LList
{
public:
    LList() { head_ = NULL; }

    class iterator {
private:
    Item<T>* curr_;
public:
    iterator& operator++();
    iterator operator++(int);
    T& operator*();
    T* operator->();
    bool operator!=(const iterator & other);
    bool operator==(const iterator & other);
};

private:
    Item<T>* head_;
    int size_;
};
```

Note: Though class iterator is defined inside LList<T>, it is completely separate and what's private to iterator can't be accessed by LList<T> and vice versa

# Outfitting LList to Support Iterators

- begin() and end() should return a new iterator that points to the head or end of the list
- But how should begin() and end() seed the iterator with the correct pointer?

```
template<typename T>
class LList
{
public:
    LList() { head_ = NULL; }

    class iterator {
private:
    Item<T>*> curr_;
public:
    iterator& operator++();
    iterator operator++(int);
    T& operator*();
    T* operator->();
    bool operator!=(const iterator & other);
    bool operator==(const iterator & other);
};

iterator begin() { ??? }
iterator end() { ??? }

private:
    Item<T>*> head_;
    int size_;
};
```

# Outfitting LList to Support Iterators

- We could add a public constructor...
- But that's bad form, because then anybody outside the LList could create their own iterator pointing to what they want it to point to...
  - Only LList<T> should create iterators
  - So what to do??

```
template<typename T>
class LList
{
public:
    LList() { head_ = NULL; }

    class iterator {
private:
    Item<T>* curr_;
public:
    iterator(Item<T>* init) : curr_(init) {}
    iterator& operator++();
    iterator operator++(int);
    T& operator*();
    T* operator->();
    bool operator!=(const iterator & other);
    bool operator==(const iterator & other);
};

iterator begin() { ??? }
iterator end() { ??? }

private:
    Item<T>* head_;
    int size_;
};
```

# Friends and Private Constructors

- Let's only have the iterator class grant access to its "trusted" friend: Llist
- Now LLList<T> can access iterators private data and member functions
- And we can add a private constructor that only 'iterator' and 'LLList<T>' can use
  - This prevents outsiders from creating iterators that point to what they choose
- Now begin() and end can create iterators via the private constructor & return them

```
template<typename T>
class LLList
{ public:
    LLList() { head_ = NULL; }

    class iterator {
    private:
        Item<T>* curr_;
        iterator(Item<T>* init) : curr_(init) {}
    public:
        friend class LLList<T>;
        iterator(Item<T>* init);
        iterator& operator++();
        iterator operator++(int);
        T& operator*();
        T* operator->();
        bool operator!=(const iterator & other);
        bool operator==(const iterator & other);
    };
    iterator begin() { iterator it(head_);
                      return it; }
    iterator end()   { iterator it(NULL);
                      return it; }

    private:
        Item<T>* head_;
        int size_;
    };
}
```

# Expanding to ArrayLists

- What internal state would an ArrayList iterator store?
- What would begin() stuff the iterator with?
- What would end() stuff the iterator with that would mean "1 beyond the end"?

# Const Iterators

- If a `LList<T>` is passed in as a `const` argument, then `begin()` and `end()` will violate the `const`'ness because they aren't declared as `const` member functions
  - `iterator begin() const;`
  - `iterator end() const;`
- While we could change them, it would violate the idea that the List will stay `const`, because once someone has an iterator they really CAN change the List's contents
- Solution: Add a second iterator type: `const_iterator`

```
template<typename T>
class LLList
{ public:
    LLList() { head_ = NULL; }

    class iterator {
    };
    // non-const member functions
    iterator begin() { iterator it(head_);
                        return it; }
    iterator end() { iterator it(NULL);
                     return it; }

private:
    Item<T>* head_;
    int size_;
};

void printMyList(const LLList<int>& mylist)
{
    LLList<int>::iterator it;
    for(it = mylist.begin(); // compile error
        it != mylist.end();
        ++it)
    { cout << *it << endl; }
}
```

# Const Iterators

- The `const_iterator` type should return references and pointers to `const T`'s
- We should add an overloaded `begin()` and `end()` that are `const` member functions and return `const_iterator`s

```
template<typename T>
class LList
{ public:
    LList() { head_ = NULL; }

    class iterator {
        ...
    };
    iterator begin();
    iterator end();

    class const_iterator {
        private:
            Item<T>* curr_;
            const_iterator(Item<T>* init);
        public:
            friend class LList<T>;
            iterator& operator++() ;
            iterator operator++(int);
            T const & operator*();
            T const * operator->();
            bool operator!=(const iterator & other);
            bool operator==(const iterator & other);
        };
        const_iterator begin() const;
        const_iterator end() const;
    };
}
```

# Const Iterators

- An updated example

```
void printMyList(const LList<int>& mylist)
{
    LList<int>::const_iterator it;
    for(it = mylist.begin(); // no more error
        it != mylist.end();
        ++it)
    {   cout << *it << endl; }
}
```

# != VS <

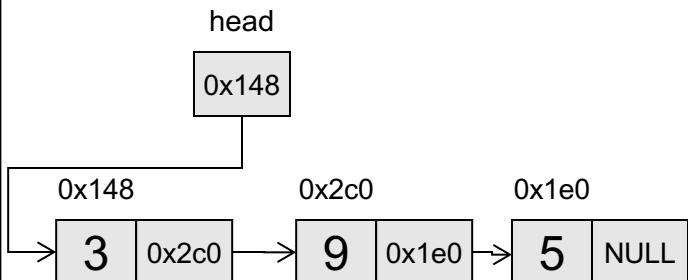

- It's common idiom to have the loop condition use != over <
- Some iterators don't support '<' comparison
  - Why? Think about what we're comparing with our LList<T>::iterator
  - We are comparing the pointer...Is the address of Item at location 1 guaranteed to be less-than the address of Item at location 2?

```
void printMyList(const LList<int>& mylist)
{
    LList<int>::const_iterator it;

    for(it = mylist.begin(); it != mylist.end(); ++it)
    { cout << *it << endl; }

    for(it = mylist.begin(); it < mylist.end(); ++it)
    { cout << *it << endl; }

}
```

# Kinds of Iterators

- This leads us to categorize iterators based on their capabilities (of the underlying data organization)
- Access type
  - Input iterators: Can only READ the value be pointed to
  - Output iterators: Can only WRITE the value be pointed to
- Movement/direction capabilities
  - Forward Iterator: Can only increment (go forward)
    - `++it`
  - Bidirectional Iterators: Can go in either direction
    - `++it` or `--it`
  - Random Access Iterators: Can jump beyond just next or previous
    - `it + 4` or `it - 2`
- Which movement/direction capabilities can our `LList<T>::iterator` naturally support

# Implicit Type Conversion

- Would the following if condition make sense?
- No! If statements want Boolean variables

```
class Student {  
    private: int id; double gpa;  
};  
int main()  
{  
    Student s1;  
    if(s1){ cout << "Hi" << endl; }  
    return 0;  
}
```

- But you've done things like this before
  - Operator>> returns an ifstream&
- So how does ifstream do it?
  - With an "implicit type conversion operator overload"
  - Student::operator bool()
    - Code to specify how to convert a Student to a bool
  - Student::operator int()
    - Code to specify how to convert a Student to an int

```
ifstream ifile(filename);  
...  
while( ifile >> x )  
{ ... }
```

```
class Student {  
    private:  
        int id; double gpa;  
    public:  
        operator bool() { return gpa>= 2.0; }  
        operator int() { return id; }  
};  
  
Student s1;  
if(s1)           // calls operator bool() and  
    int x = s1; // calls operator int()
```

# Iterators With Implicit Conversions

- Can use operator bool() for iterator

```
template<typename T>
class LList
{ public:
    LList() { head_ = NULL; }

    class iterator {
    private:
        Item<T>* curr_;
    public:
        operator bool()
        { return curr_ != NULL; }
    };
};

void printMyList(LList<int>& mylist)
{
    LList<int>::iterator it = mylist.begin();
    while(it){
        cout << *it++ << endl;
    }
}
```

# Finishing Up

- Iterators provide a nice abstraction between user and underlying data organization
  - Wait until we use trees and other data organizations
- Due to their saved internal state they can be more efficient than simpler approaches [ like `get(i)` ]
